#### Abstract

The spin and parity of the $Z_{c}(3900)^{ \pm}$state are determined to be $J^{P}=1^{+}$with a statistical significance larger than $7 \sigma$ over other quantum numbers in a partial wave analysis of the process $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} J / \psi$. We use a data sample of $1.92 \mathrm{fb}^{-1}$ accumulated at $\sqrt{s}=4.23$ and 4.26 GeV with the BESIII experiment. When parameterizing the $Z_{c}(3900)^{ \pm}$with a Flatté-like formula, we determine its pole mass $M_{\text {pole }}=\left(3881.2 \pm 4.2_{\text {stat }} \pm 52.7_{\text {syst }}\right) \mathrm{MeV} / c^{2}$ and pole width $\Gamma_{\text {pole }}=(51.8 \pm$ $\left.4.6_{\text {stat }} \pm 36.0_{\text {syst }}\right) \mathrm{MeV}$. We also measure cross sections for the process $e^{+} e^{-} \rightarrow Z_{c}(3900)^{+} \pi^{-}+$ c.c. $\rightarrow J / \psi \pi^{+} \pi^{-}$and determine an upper limit at the $90 \%$ confidence level for the process $e^{+} e^{-} \rightarrow$ $Z_{c}(4020)^{+} \pi^{-}+c . c . \rightarrow J / \psi \pi^{+} \pi^{-}$.

PACS numbers: $14.40 . \mathrm{Rt}, 13.66 . \mathrm{Bc}, 14.40 . \mathrm{Pq}$

A charged charmoniumlike state, $Z_{c}^{ \pm}\left(Z_{c}\right.$ denotes ${ }_{146}$ $Z_{c}(3900)$ throughout this Letter except when its mass is ${ }_{147}$ explicitly mentioned), was observed by the BESIII [1] and ${ }_{148}$ Belle [2] collaborations in the process $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} J / \psi_{149}$ and confirmed using CLEO-c's data [3]. As there are at150 least four quarks in the structure, many theoretical inter-151 pretations of the nature and the decay dynamics of the ${ }_{152}$ $Z_{c}$ have been put forward [4-9].

A similar charged structure, the $Z_{C}(3885)^{ \pm}$, was ob- ${ }^{154}$ served in the process $e^{+} e^{-} \rightarrow\left(D \bar{D}^{*}\right)^{ \pm} \pi^{\mp}[10]$, with spin ${ }^{155}$ parity $\left(J^{P}\right)$ assignment of $1^{+}$favored over the $1^{-}$and ${ }^{156}$ $0^{-}$hypotheses. However, its mass and width are $2 \sigma^{157}$ and $1 \sigma$, respectively, below those of the $Z_{c}^{ \pm}$observed in ${ }^{158}$ $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} J / \psi$. Are the $Z_{c}(3885)^{ \pm}$and the $Z_{c}^{ \pm}$the ${ }^{159}$ same state and do they have the same spin and parity? This is one of the most important pieces of information ${ }^{160}$ desired in many theoretical analyses $[6,11]$. Finally, the ${ }^{161}$ $Z_{c}(4020)$ was observed for the first time in the processes ${ }^{162}$ $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} h_{c}[12]$ and $e^{+} e^{-} \rightarrow\left(D^{*} \bar{D}^{*}\right)^{ \pm} \pi^{\mp}$ [13], but ${ }^{163}$ it has not been searched for in the $\pi^{+} \pi^{-} J / \psi$ final state ${ }^{164}$ yet.

In this Letter, we report on the determination of spin $\sin _{167}$ and parity of the $Z_{c}$ and a search for the $Z_{c}(4020)^{{ }_{168}}$
in the process $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} J / \psi$. The results are based on a partial wave analysis (PWA) of the $e^{+} e^{-} \rightarrow$ $\pi^{+} \pi^{-} J / \psi$ events accumulated with the BESIII detector [14]. The BESIII detector consists of a helium-gasbased drift chamber (MDC), a plastic scintillator time-of-flight system, and a $\mathrm{CsI}(\mathrm{Tl})$ electromagnetic calorimeter (EMC), all enclosed in a superconducting solenoidal magnet providing a $1.0-\mathrm{T}$ magnetic field. The solenoid is supported by an octagonal flux-return yoke with resistive plate counter muon identifier modules interleaved with steel. The data sample includes $1092 \mathrm{pb}^{-1} e^{+} e^{-}$collision data at a center-of-mass (c.m.) energy $\sqrt{s}=4.23 \mathrm{GeV}$, and $827 \mathrm{pb}^{-1}$ data at $\sqrt{s}=4.26 \mathrm{GeV}$ [15]. The precise c.m. energies are measured with the di-muon process [16].

The $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} J / \psi$ candidate events are selected with the same selection criteria as described in Refs. [1, 17] with $J / \psi$ reconstructed from lepton pairs $\left(\ell^{+} \ell^{-}=\mu^{+} \mu^{-}, e^{+} e^{-}\right)$. The numbers of selected candidate events are 4154 at $\sqrt{s}=4.23 \mathrm{GeV}$ and 2447 at $\sqrt{s}=4.26 \mathrm{GeV}$; the event samples are estimated to contain 365 and 272 background events, respectively, at these two points, using the $J / \psi$ mass sidebands as has been done in Ref. [1].

Amplitudes of the PWA are constructed with the $2_{201}$ helicity-covariant method [18]; the process $e^{+} e^{-} \rightarrow_{202}$ $\pi^{+} \pi^{-} J / \psi$ is assumed to proceed via the $Z_{c}$ resonance,203 i.e., $e^{+} e^{-} \rightarrow Z_{c}^{ \pm} \pi^{\mp}, Z_{c}^{ \pm} \rightarrow J / \psi \pi^{ \pm}$, and via the non-204 $Z_{c}$ decay $e^{+} e^{-} \rightarrow R J / \psi, R \rightarrow \pi^{+} \pi^{-}$. All processes205 are added coherently to obtain the total amplitude [19].206 For a particle decaying to the two-body final state, i.e.,207 $A(J, m) \rightarrow B(s, \lambda) C(\sigma, \nu)$, where spin and helicity are ${ }_{208}$ indicated in the parentheses, its helicity amplitude $F_{\lambda, \nu 209}$ is related to the covariant amplitude via $[18,20]$

$$
\begin{equation*}
F_{\lambda, \nu}=\sum_{l S} g_{l S} \sqrt{\frac{2 l+1}{2 J+1}}\langle l 0 S \delta \mid J \delta\rangle\langle s \lambda \sigma-\nu \mid S \delta\rangle r^{l}{\frac{B_{l}(r)}{B_{l}\left(r_{0}\right)},^{211}}_{211}^{213} \tag{1}
\end{equation*}
$$ where $\delta=\lambda-\nu$, and $g_{l S}$ is the coupling constant in the $l_{-215}$ $S$ coupling scheme, the angular brackets denote Clebsch-216 Gordan coefficients, $r$ is the magnitude of the momen-217 tum difference between the two final state particles, $r_{0218}$ corresponds to the momentum difference at the nominal $l_{219}$ mass of the resonance, and $B_{l}$ is a barrier factor [21]..220 The nonresonant process, $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} J / \psi$, is param-221 eterized with an amplitude based on the QCD multipole ${ }_{222}$ expansion [22].

The relative magnitudes and phases of the complex ${ }^{224}$ coupling constants $g_{l S}$ are determined by an unbinned ${ }^{225}$ maximum likelihood fit to data. The minimization is ${ }^{226}$ performed using the package MINUIT [23], and the back-227 grounds are subtracted from the likelihood as in Ref. [24].228

In the nominal fit, we assume the $Z_{c}$ to have $J^{P}=1^{+},{ }^{229}$ and its lineshape is described with a Flatté-like formula ${ }^{230}$ taking into account the fact that the $Z_{c}^{ \pm}$decays are dom-231 inated by the final states $\left(D \bar{D}^{*}\right)^{ \pm}[10]$ and $J / \psi \pi^{ \pm}[1], 232$ i.e.,

$$
\begin{equation*}
B W\left(s, M, g_{1}^{\prime}, g_{2}^{\prime}\right)=\frac{1}{s-M^{2}+i\left[g_{1}^{\prime} \rho_{1}(s)+g_{2}^{\prime} \rho_{2}(s)\right]} \tag{2}
\end{equation*}
$$

where the subscripts in $g_{i}^{\prime}(i=1,2)$ represent the $Z_{c}^{ \pm} \rightarrow^{237}$ $\pi^{ \pm} J / \psi$ and $\left(D \bar{D}^{*}\right)^{ \pm}$decays, respectively; $\rho_{i}(s)=2 k_{i} / \sqrt{s}^{239}$ is a kinematic factor with $k_{i}$ being the magnitude of the ${ }^{239}$ three-vector momentum of the final state particle $\left(J / \psi^{240}\right.$ or $D$ ) in the $Z_{c}$ rest frame; and $g_{1}^{\prime}$ and $g_{2}^{\prime}$ are the cou- ${ }^{241}$ pling strengths of $Z_{c}^{ \pm} \rightarrow \pi^{ \pm} J / \psi$ and $Z_{c}^{ \pm} \rightarrow\left(D \bar{D}^{*}\right)^{ \pm}{ }^{242}$ respectively, which will be determined by the fit to data. ${ }_{244}^{243}$

To describe the $\pi^{+} \pi^{-}$mass spectrum, four reso- ${ }_{245}$ nances, $\sigma, f_{0}(980), f_{2}(1270)$ and $f_{0}(1370)$, are intro- ${ }_{246}$ duced. $f_{0}(980)$ is described with a Flatté formula [25] ${ }_{247}$ and the others are described with relativistic Breit- ${ }_{248}$ Wigner (BW) functions. The width of the wide resonance ${ }_{249}$ $\sigma$ is parameterized with $\Gamma_{\sigma}(s)=\sqrt{1-\frac{4 m_{\pi}^{2}}{s}} \Gamma[26,27],{ }^{250}$ and the masses and widths for the $f_{2}(1270)$ and $f_{0}(1370)_{251}$ are taken from the Particle Data Group (PDG) [28]. The 252 statistical significance for each resonance is determined ${ }_{253}$ by examining the probability of the change in $\log$ likeli-254 hood $(\log L)$ values between including and excluding this $2_{25}$
resonance in the fits, and the probability is calculated under the $\chi^{2}$ distribution hypothesis taking the change of the number of degrees of freedom $\Delta$ (ndf) into account. With this procedure, the statistical significance of each of these states and the nonresonant process is estimated to be larger than $5 \sigma$. All of them are therefore included in the nominal fit, which includes the $e^{+} e^{-} \rightarrow \sigma J / \psi$, $f_{0} J / \psi, f_{0}(1370) J / \psi, f_{2}(1270) J / \psi, Z_{c}^{ \pm} \pi^{\mp}$ and nonresonant processes.

A simultaneous fit is performed to the two data sets. The coupling constants are set as free parameters and are allowed to be different at the two energy points except for the common ones describing $Z_{c}$ decays. The oppositely charged $Z_{c}$ states are regarded as isospin partners; they share a common mass and coupling parameters $g_{1}^{\prime}$ and $g_{2}^{\prime}$. Figure 1 shows projections of the fit results at $\sqrt{s}=4.23$ and 4.26 GeV , with fit goodness of the Dalitz plot $\chi^{2} / \mathrm{ndf}=1.3$ and 1.2 , respectively. The mass of $Z_{c}^{ \pm}$ is measured to be $M_{Z_{c}}=\left(3901.5 \pm 2.7_{\text {stat }}\right) \mathrm{MeV} / c^{2}$ and the coupling parameters $g_{1}^{\prime}=\left(0.075 \pm 0.006_{\text {stat }}\right) \mathrm{GeV}^{2}$ and $g_{2}^{\prime} / g_{1}^{\prime}=27.1 \pm 2.0_{\text {stat }}$. This measurement is consistent with the previous result $g_{2}^{\prime} / g_{1}^{\prime}=27.1 \pm 13.1$ estimated based on the measured decay width ratio $\Gamma\left(Z_{c}^{ \pm} \rightarrow\right.$ $\left.\left(D \bar{D}^{*}\right)^{ \pm}\right) / \Gamma\left(Z_{c}^{ \pm} \rightarrow J / \psi \pi^{ \pm}\right)=6.2 \pm 2.9[10]$. If the $Z_{c}^{ \pm}$is parameterized as a constant width BW function, the simultaneous fit gives a mass of $\left(3897.6 \pm 1.2_{\text {stat }}\right) \mathrm{MeV} / c^{2}$ and a width of $\left(43.5 \pm 1.5_{\text {stat }}\right) \mathrm{MeV}$, but the value of $-\ln L$ increases by 22 with $\Delta($ ndf $)=1$. The BW parametrization is thus disfavored with a significance of $6.6 \sigma$.

Figure 2 shows the polar angle $\left(\theta_{Z_{c}^{ \pm}}\right)$distribution of $Z_{c}^{ \pm}$in the process $e^{+} e^{-} \rightarrow Z_{c}^{+} \pi^{-}+c . c$. and the helicity angle $\left(\theta_{J / \psi}\right)$ distribution in the decay $Z_{c}^{ \pm} \rightarrow \pi^{ \pm} J / \psi$ for the combined data within the $Z_{c}$ mass region $m_{J / \psi \pi^{ \pm}} \in$ $(3.86,3.92) \mathrm{GeV} / c^{2}$, where $\theta_{J / \psi}$ is the angle between the momentum of $J / \psi$ in the $Z_{c}$ rest frame and the $Z_{c}$ momentum in the $e^{+} e^{-}$rest frame. The fit results, using different assumptions for the $Z_{c}$ spin and parity, are drawn with a global normalization factor. The distribution indicates that data favors a spin and parity assignment of $1^{+}$ for the $Z_{c}^{ \pm}$. The significance of the $Z_{c}^{ \pm}\left(1^{+}\right)$hypothesis is further examined using the hypothesis test [29], in which the alternative hypothesis is our nominal fit with an additional $Z_{c}^{ \pm}\left(J^{P} \neq 1^{+}\right)$state. Possible $J^{P}$ assignments, other than $1^{+}$, are $0^{-}, 1^{-}, 2^{-}$, and $2^{+}$. The changes $-2 \Delta \ln L$ when the $Z_{c}\left(1^{+}\right) \pi^{\mp}$ amplitude is removed from the alternative hypothesis are listed in Table I. Using the associated change in the ndf when the $Z_{c}^{ \pm}\left(1^{+}\right)$is excluded, we determine the significance of the $1^{+}$hypothesis over the alternative $J^{P}$ possibilities to be larger than $7 \sigma$.

The fit results shown in Fig. 1 indicate that process is dominated by the $\pi \pi S$-wave resonances, i.e. the $\sigma$, $f_{0}(980)$ and $f_{0}(1370)$. The fraction of all $\pi^{+} \pi^{-} S$-wave components including the interference between them is measured to be $\left(61.7 \pm 2.1_{\text {stat }}\right) \%$ of the total $\pi^{+} \pi^{-} J / \psi$

FIG. 1: (color online) Projections to $m_{\pi^{+} \pi^{-}}(\mathrm{a}, \mathrm{c})$ and $m_{J / \psi \pi^{ \pm}}(\mathrm{b}, \mathrm{d})$ of the fit results with $J^{P}=1^{+}$for the $Z_{c}$, at $\sqrt{s}=4.23 \mathrm{GeV}$ ( $\mathrm{a}, \mathrm{b}$ ) and $\sqrt{s}=4.26 \mathrm{GeV}(\mathrm{c}, \mathrm{d})$. The points with error bars are data, and the black histograms are the total fit results including backgrounds. The shaded histogram denotes backgrounds. The contributions from the $\pi^{+} \pi^{-} S$-wave $J / \psi, f_{2}(1270) J / \psi$, and $Z_{c}^{ \pm} \pi^{\mp}$, are shown in the plots. The $\pi^{+} \pi^{-} S$-wave resonances include the $\sigma, f_{0}(980)$ and $f_{0}(1370)$. Plots (b) and (d) are filled with two entries ( $m_{J / \psi \pi^{+}}$and $m_{J / \psi \pi^{-}}$) per event.

TABLE I: Significance of the spin parity $1^{+}$over other quan- ${ }^{259}$ tum numbers for $Z_{c}^{ \pm}$. The significance is obtained for given ${ }^{260}$ change in ndf, $\Delta(\mathrm{ndf})$. In each case, $\Delta(\mathrm{ndf})=2 \times 4+5$, where ${ }^{261}$ $2 \times 4$ ndf account for the coupling strength for $e^{+} e^{-} \rightarrow Z_{c}^{ \pm} \pi^{\mp}{ }^{262}$ at the two data sets, and the additional five ndf are the contribution of the common degrees of freedom for the $Z_{c}$ resonant parameters and the coupling strength for $Z_{c}^{ \pm} \rightarrow J / \psi \pi^{ \pm}$.

| Hypothesis | $\Delta(-2 \ln L)$ | $\Delta($ ndf $)$ | Significance |
| :--- | :---: | :---: | :---: |
| $1^{+}$over $0^{-}$ | 94.0 | 13 | $7.6 \sigma$ |
| $1^{+}$over 1- | 158.3 | 13 | $10.8 \sigma$ |
| $1^{+}$over 2 | 151.9 | 13 | $10.5 \sigma$ |
| $1^{+}$over $2^{+}$ | 96.0 | 13 | $7.7 \sigma$ | 60

$\qquad$ are GeV . Here, the errors are statistical only, and they are estimated using the covariance matrix from the fits.

To measure amplitudes associated with the polarization of $Z_{c}^{ \pm}$in $e^{+} e^{-} \rightarrow Z_{c}^{ \pm} \pi^{\mp}$ and that of $J / \psi$ in $Z_{c}^{ \pm} \rightarrow J / \psi \pi^{ \pm}$decays in the nominal fit, the ratios of helicity amplitudes with different polarizations as defined in Eq. (1) are calculated to be $\left|F_{1,0}^{Z_{c}}\right|^{2} /\left|F_{0,0}^{Z_{c}}\right|^{2}=$ $0.22 \pm 0.05_{\text {stat }}$ at 4.23 GeV , and $0.21 \pm 0.11_{\text {stat }}$ at 4.26 GeV for $e^{+} e^{-} \rightarrow Z_{c}^{ \pm} \pi^{\mp}$, and $\left|F_{1,0}^{\psi}\right|^{2} /\left|F_{0,0}^{\psi}\right|^{2}=0.45 \pm 0.15_{\text {stat }}$ for $Z_{c}^{ \pm} \rightarrow J / \psi \pi^{ \pm}$, at both energy points. Here $F_{1,0}^{Z_{c} / \psi}$ and $F_{0,0}^{Z_{c} / \psi}$ correspond to transverse and longitudinal polarization amplitudes in the decay, respectively. The results show that the $Z_{c}$ polarization is dominated by the longitudinal component.

FIG. 2: (color online) (a) Polar angle distribution of $Z_{c}^{ \pm}$in the ${ }^{322}$ process $e^{+} e^{-} \rightarrow Z_{c}^{+} \pi^{-}+$c.c., (b) helicity angle distribution ${ }^{323}$ of $J / \psi$ in the $Z_{c}^{ \pm} \rightarrow \pi^{ \pm} J / \psi$. The dots with error bars show 324 the combined data with requirement $m_{J / \psi \pi^{ \pm}} \in(3.86,3.92)_{325}$ $\mathrm{GeV} / c^{2}$, and compared to the total fit results with different326 $J^{P}$ hypotheses.

The Born cross section for $Z_{c}$ production is measured ${ }^{329}$ with the relation $\sigma=N_{Z_{c}^{ \pm}} /(\mathcal{L}(1+\delta) \epsilon \mathcal{B})$, where $N_{Z_{c}^{ \pm}}$is ${ }^{330}$ the signal yield for the process $e^{+} e^{-} \rightarrow Z_{c}^{+} \pi^{-}+$c.c. $\rightarrow^{331}$ $\pi^{+} \pi^{-} J / \psi, \mathcal{L}$ is the integrated luminosity, and $\epsilon$ is the ${ }^{332}$ detection efficiency obtained from a MC simulation which ${ }^{333}$ is generated using the amplitude parameters determined ${ }^{334}$ in the PWA. The radiative correction factor $(1+\delta)$ is ${ }^{335}$ determined to be 0.818 [1]. The Born cross section is ${ }^{336}$ measured to be $\left(22.0 \pm 1.0_{\text {stat }}\right) \mathrm{pb}$ at $\sqrt{s}=4.23 \mathrm{GeV}$ and $_{337}$ $\left(11.0 \pm 1.2_{\text {stat }}\right) \mathrm{pb}$ at $\sqrt{s}=4.26 \mathrm{GeV}$.

Using these two data sets, we also search for the pro-339 cess $e^{+} e^{-} \rightarrow Z_{c}(4020)^{+} \pi^{-}+c . c . \rightarrow \pi^{+} \pi^{-} J / \psi$, with the ${ }^{340}$ $Z_{c}(4020)^{ \pm}$assumed to be a $1^{+}$state. In the PWA, its ${ }^{341}$ mass is taken from Ref. [12], and its width is taken as the ${ }^{342}$ observed value, which includes the detector resolution. ${ }^{343}$ The statistical significance for $Z_{c}(4020)^{ \pm} \rightarrow J / \psi \pi^{ \pm}$is ${ }^{344}$ found to be $3 \sigma$ in the combined data. The Born $\operatorname{cross}_{345}$ sections are measured to be $\left(0.2 \pm 0.1_{\text {stat }}\right) \mathrm{pb}$ at $4.23_{346}$ GeV and $\left(0.8 \pm 0.4_{\text {stat }}\right) \mathrm{pb}$ at $s=4.26 \mathrm{GeV}$, and the cor ${ }_{-347}$ responding upper limits at the $90 \%$ confidence level are $_{348}$ estimated to be 0.9 pb and 1.4 pb , respectively.

Systematic errors associated with the event selection,350 including the luminosity measurement, tracking efficien- ${ }_{351}$ cy of charged tracks, kinematic fit, initial state radia- ${ }_{352}$ tion (ISR) correction factor and the branching fraction ${ }_{353}$ of $\operatorname{Br}\left(J / \psi \rightarrow \ell^{+} \ell^{-}\right)$, have been estimated to be $4.8 \%$ for $_{354}$ the cross section measurement and 1.8 MeV for the $Z_{C_{355}}$ mass in the previous analysis [1].

Uncertainties associated with the amplitude analy- ${ }_{357}$ sis come from the $\sigma$ and $Z_{c}$ parametrizations, the $\mathrm{e}_{358}$ background estimation, the parameters in the $f_{0}(980)_{359}$ Flatté formula, the barrier radius in the barrier factor, ${ }_{360}$ the mass resolution and the component of non-resonant ${ }_{361}$ amplitude.

The systematic uncertainty due to the $\sigma$ lineshape is ${ }_{363}$
estimated by comparing the nominal fit with two other parameterizations, the PKU ansatz [30] and the ZouBugg approach [31]. The differences in the $Z_{c}$ signal yields and mass measurement are taken as the errors, which are $2.5 \%(31.0 \%)$ for the signal yields at 4.23 (4.26) GeV and 19.5 MeV for the $Z_{c}$ mass.

The uncertainty due to the $f_{0}(980)$ lineshape is estimated by varying the couplings by $1 \sigma$ as determined in the decays $J / \psi \rightarrow \phi \pi^{+} \pi^{-}$and $\phi K^{+} K^{-}$[25]. Uncertainties associated with the $f_{0}(1370)$ are estimated by varying the mass and width by one standard deviation around the world average values [28].

The uncertainty due to the $Z_{c}$ parametrization is estimated by using a constant-width relativistic BW function. The simultaneous fit gives the $Z_{c}$ mass of ( $3897.6 \pm$ $\left.1.2_{\text {stat }}\right) \mathrm{MeV} / c^{2}$ and the width of $\left(43.5 \pm 1.5_{\text {stat }}\right) \mathrm{MeV}$. The difference in the $Z_{c}$ signal yields is $15.5 \%$ ( $7.9 \%$ ) for the data taken at 4.23 (4.26) GeV.

The uncertainty due to the background level is estimated by changing the number of background events by $1 \sigma$ around the nominal value, that is, $\pm 25$ around 637 events.

The barrier radius is usually taken in the range $r_{0} \in$ $(0.25,0.76) \mathrm{fm}$, with 0.6 fm being used in the nominal fit. Uncertainties at both ends are checked. For a conservative estimation, the radius $r_{0}=0.76 \mathrm{fm}$, which results in the larger difference, is used to estimate the uncertainty.

The uncertainty due to the mass resolution in the $J / \psi \pi$ invariant mass is estimated with an unfolded $Z_{c}$ width. A truth width is unfolded from the observed $Z_{c}$ width using a relation determined by the MC simulation, and its difference from the unfolded width, $\delta \Gamma / \Gamma=\delta g_{1}^{\prime} / g_{1}^{\prime}$, is taken as the systematic uncertainty for the coupling constant $g_{1}^{\prime}$. The uncertainties in the signal yields and the $Z_{c}$ mass are determined with the truth coupling constant.

The nonresonant process is described with a formula derived from the QCD multipole expansion [22]. It includes the $S$ - and $D$-wave components. The uncertainty associated with this amplitude is estimated by removing the insignificant $D$-wave component and using the $S$-wave component only.

Table II summarizes the systematic uncertainties. Assuming all of these sources are independent, the total systematic uncertainties are 38.0 MeV for the measurement of the $Z_{c}$ mass, and $20.3 \%(49.2 \%)$ for the measurement of $Z_{c}$ cross sections at $\sqrt{s}=4.23(4.26) \mathrm{GeV}$.

In summary, with $1.92 \mathrm{fb}^{-1}$ data taken at $\sqrt{s}=4.23$ and 4.26 GeV , the $Z_{c}^{ \pm}$state is studied with an amplitude fit to the $e^{+} e^{-} \rightarrow \pi^{+} \pi^{-} J / \psi$ samples, and its spin and parity have been determined to be $1^{+}$ with a statistical significance larger than $7 \sigma$ over other quantum numbers. The mass is measured to be $M_{Z_{c}}=\left(3901.5 \pm 2.7_{\text {stat }} \pm 38.0_{\text {syst }}\right) \mathrm{MeV} / c^{2}$ in the parametrization of a Flatté-like formula with parameters

TABLE II: Summary of systematic uncertainties on the ${ }_{401}^{400}$ $Z_{c}\left(J^{P}=1^{+}\right)$mass $M_{Z_{c}}\left(\mathrm{MeV} / c^{2}\right)$, parameters $g_{1}^{\prime}\left(\mathrm{GeV}^{2}\right)_{402}^{401}$ and $g_{2}^{\prime} / g_{1}^{\prime}$, and the signal yields at $4.23 \mathrm{GeV}\left(N_{Z_{c}}^{\mathrm{I}}\right)$ and $4.26_{403}^{402}$ $\mathrm{GeV}\left(N_{Z_{c}}^{\mathrm{II}}\right)$. The uncertainties shown for the $Z_{c}$ mass, $\mathrm{pa}^{-}{ }_{404}$ rameter $g_{1}^{\prime}$ and the ratio $g_{2}^{\prime} / g_{1}^{\prime}$ are absolute values, while the ${ }_{405}$ uncertainties for $N_{Z_{c}}^{\mathrm{I}}$ and $N_{Z_{c}}^{11}$ are relative ones.
